Review Questions

1. 1. Why can't you return an array from a function in C?

   If another function modifies that array, then that exact memory address is modified instead of a copy (like with integers, floats, pointers, etc). This can lead to undefined/problematic behaviour (e.g. example from class).
2. 2. What happens if you dereference a pointer to NULL (addr 0x0) in C?

   In most cases, you will get a segmentation fault (or some form of crash) because addr 0x0 is a reserved location
3. 3. If I take a hash of a video I recorded on my phone, then I modify the video with an AI tool, but I only make a minor change that only affects a few bits of the video, will I get a differerent hash result?

   In most cases, the hash result will be different. A good hash function is designed to return different outputs for different inputs. In particular, if you have a similar input, an ideal hash function will return a completely different unrelated output.
